The score

Comparing

two binomial proportions

Bayesian and likelihood analysis of tw proportions

- 1 Tests for a binomial proportion
- Score test versus Wald
- 3 Exact binomial test
- 4 Tests for differences in binomial proportions
- 6 Intervals for differences in binomial proportions

Exact tes

Comparing two binomial proportions

Bayesian and likelihood analysis of tw proportions

### Motivation

- Consider a randomized trial where 40 subjects were randomized (20 each) to two drugs with the same active ingredient but different expedients
- Consider counting the number of subjects with side effects for each drug

	Side		
	Effects	None	total
Drug A	11	9	20
Drug B	5	15	20
Total	16	14	40

Exact tes

Comparing two binomia proportions

Bayesian and likelihood analysis of tw proportions

# Hypothesis tests for binomial proportions

- Consider testing  $H_0$ :  $p = p_0$  for a binomial proportion
- The **score** test statistic

$$\frac{\hat{p}-p_0}{\sqrt{p_0(1-p_0)/n}}$$

follows a Z distribution for large n

This test performs better than the Wald test

$$\frac{\hat{p}-p_0}{\sqrt{\hat{p}(1-\hat{p})/n}}$$

Bayesian and likelihood analysis of tw proportions

# Inverting the two intervals

Inverting the Wald test yields the Wald interval

$$\hat{p} \pm Z_{1-\alpha/2} \sqrt{\hat{p}(1-\hat{p})/n}$$

Inverting the Score test yields the Score interval

$$\hat{\rho}\left(\frac{n}{n+Z_{1-\alpha/2}^2}\right) + \frac{1}{2}\left(\frac{Z_{1-\alpha/2}^2}{n+Z_{1-\alpha/2}^2}\right)$$

$$\pm Z_{1-\alpha/2} \sqrt{\tfrac{1}{n+Z_{1-\alpha/2}^2} \left[ \hat{p} \big(1-\hat{p}\big) \left( \tfrac{n}{n+Z_{1-\alpha/2}^2} \right) + \tfrac{1}{4} \left( \tfrac{Z_{1-\alpha/2}^2}{n+Z_{1-\alpha/2}^2} \right) \right]}$$

• Plugging in  $Z_{\alpha/2} = 2$  yields the Agresti/Coull interval

The score

statistic

Exact tes

Comparing two binomial

Bayesian and likelihood analysis of tw  In our previous example consider testing whether or not Drug A's percentage of subjects with side effects is greater than 10%

•  $H_0: p_A = .1 \text{ verus } H_A: p_A > .1$ 

- $\hat{p} = 11/20 = .55$
- Test Statistic

$$\frac{.55 - .1}{\sqrt{.1 \times .9/20}} = 6.7$$

• Reject, pvalue =  $P(Z > 6.7) \approx 0$ 

Comparing two binomial proportions

Bayesian and likelihood analysis of tw proportions

## Exact binomial tests

- Consider calculating an exact P-value
- What's the probability, under the null hypothesis, of getting evidence as extreme or more extreme than we obtained?

$$P(X_A \ge 11) = \sum_{x=11}^{20} {20 \choose x} .1^x \times .9^{20-x} \approx 0$$

- pbinom(10, 20, .1, lower.tail = FALSE)
- binom.test(11, 20, .1, alternative =
   "greater")

Exact tests

Comparing two binomial proportions

Bayesian and likelihood analysis of tw proportions

### Notes on exact binomial tests

- This test, unlike the asymptotic ones, guarantees the Type I error rate is less than desired level; sometimes it is much less
- Inverting the exact binomial test yields an exact binomial interval for the true proprotion
- This interval (the Clopper/Pearson interval) has coverage greater than 95%, though can be very conservative
- For two sided tests, calculate the two one sided P-values and double the smaller

Comparing two binomia proportions

Bayesian and likelihood analysis of tw proportions

# Wald versus Agrest/Coull<sup>1</sup>

Bayesian and likelihood analysis of two proportions

# Comparing two binomials

- Consider now testing whether the proportion of side effects is the same in the two groups
- Let  $X \sim \operatorname{Binomial}(n_1, p_1)$  and  $\hat{p}_1 = X/n_1$
- Let  $Y \sim \operatorname{Binomial}(n_2, p_2)$  and  $\hat{p}_2 = Y/n_2$
- We also use the following notation:

$n_{11} = X$	$n_{12}=n_1-X$	$n_1=n_{1+}$
$n_{21} = Y$	$n_{22}=n_2-Y$	$n_2 = n_{2+}$
$n_{2+}$	$n_{+2}$	

Bayesian and likelihood analysis of tw proportions

## Comparing two proportions

- Consider testing  $H_0: p_1 = p_2$
- Versus  $H_1: p_1 \neq p_2, H_2: p_1 > p_2, H_3: p_1 < p_2$
- The score test statstic for this null hypothesis is

$$TS = rac{\hat{
ho}_1 - \hat{
ho}_2}{\sqrt{\hat{
ho}(1-\hat{
ho})(rac{1}{n_1} + rac{1}{n_2})}}$$

where  $\hat{p} = \frac{X+Y}{n_1+n_2}$  is the estimate of the common proportion under the null hypothesis

• This statistic is normally distributed for large  $n_1$  and  $n_2$ .

The sco

Exact test

Comparing two binomial proportions

Bayesian and likelihood analysis of tw proportions

- This interval does not have a closed form inverse for creating a confidence interval (though the numerical interval obtained performs well)
- An alternate interval inverts the Wald test

$$TS = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\frac{\hat{p}_1(1-\hat{p}_1)}{n_1} + \frac{\hat{p}_2(1-\hat{p}_2)}{n_2}}}$$

• The resulting confidence interval is

$$\hat{
ho}_1 - \hat{
ho}_2 \pm Z_{1-lpha/2} \sqrt{rac{\hat{
ho}_1(1-\hat{
ho}_1)}{n_1} + rac{\hat{
ho}_2(1-\hat{
ho}_2)}{n_2}}$$

Bayesian and likelihood analysis of tw proportions

## Continued

- As in the one sample case, the Wald iterval and test performs poorly relative to the score interval and test
- For testing, always use the score test
- For intervals, inverting the score test is hard and not offered in standard software
- A simple fix is the Agresti/Caffo interval which is obtained by calculating  $\tilde{p}_1 = \frac{x+1}{n_1+2}$ ,  $\tilde{n}_1 = n_1+2$ ,  $\tilde{p}_2 = \frac{y+1}{n_2+2}$  and  $\tilde{n}_2 = (n_2+2)$
- Using these, simply construct the Wald interval
- This interval does not approximate the score interval, but does perform better than the Wald interval

Outlin

Exact tes

Comparing two binomial proportions

Bayesian and likelihood analysis of tw proportions  Test whether or not the proportion of side effects is the same for the two drugs

• 
$$\hat{p}_A = .55$$
,  $\hat{p}_B = 5/20 = .25$ ,  $\hat{p} = 16/40 = .4$ 

Test statistic

$$\frac{.55 - .25}{\sqrt{.4 \times .6 \times \left(1/20 + 1/20\right)}} = 1.61$$

- Fail to reject  $H_0$  at .05 level (compare with 1.96)
- P-value  $P(|Z| \ge 1.61) = .11$

Comparing two binomial proportions

# Wald versus Agrest/Caffo<sup>2</sup>

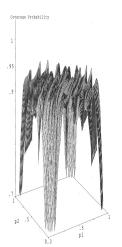

Figure 7. Coverage probabilities for 95% nominal Wald confidence interval as a function of p1 and p2, when n1 = n2 = 10.

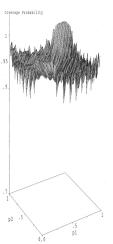

Figure 8. Coverage probabilities for 95% nominal adjusted confidence interval (adding t = 4 pseudo observations) as a function of p1 and p2, when n1 = n2 = 10,

# Wald versus Agrest/Caffo<sup>3</sup>

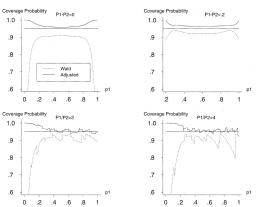

Figure 6. Coverage probabilities for nominal 95% Wald and adjusted confidence intervals (adding t = 4 pseudo observations) as a function of p1 when p1 - p2 = 0 or .2 and when p1/p2 = 2 or 4, for n1 = n2 = 10.

xact tes

Comparing two binomia proportions

Bayesian and likelihood analysis of two proportions

# Bayesian and likelihood inference for two binomial proportions

- Likelihood analysis requires the use of profile likelihoods, or some other technique and so we omit their discussion
- Consider putting independent Beta $(\alpha_1, \beta_1)$  and Beta $(\alpha_2, \beta_2)$  priors on  $p_1$  and  $p_2$  respectively
- Then the posterior is

$$\pi(p_1, p_2) \propto p_1^{x+\alpha_1-1} (1-p_1)^{n_1+\beta_1-1} \times p_2^{y+\alpha_2-1} (1-p_2)^{n_2+\beta_2-1}$$

- Hence under this (potentially naive) prior, the posterior for p<sub>1</sub> and p<sub>2</sub> are independent betas
- The easiest way to explore this posterior is via Monte Carlo simulation
