Varianc

Chebyshev's inequality

Expected values

- The expected value or mean of a random variable is the center of mass of its distribution
- For discrete random variable X with PMF p(x), it is defined as follows

$$E[X] = \sum_{x} xp(x) = \sum_{\text{possible values of X}} xP(X = x)$$

where the sum is taken over the possible values of x

- E[X] represents the center of mass of a collection of locations and weights, $\{x, p(x)\}$
- E[X] is not necessarily among the values that the variable X takes

Chebyshev's

Example

variables

Continuous random variables

Rules abou expected values

Variance

Chebyshev's inequality

Expected values

$$E[X] = \sum_{x} x p(x)$$

•
$$E(X_1) = (-4) \times 0.25 + (-3) \times 0.25 + 3 \times 0.25 + 4 \times 0.25 = 0$$

•
$$E(X_2) = (-4) \times 0.25 + 1 \times 0.25 + 2 \times 0.25 + 3 \times 0.25 = 0.5$$

•
$$E(X_3) = (-4) \times 0.60 + 1 \times 0.20 + 2 \times 0.15 + 3 \times 0.05 = -1.75$$

•
$$E(X_4) = (-4) \times 0.05 + 1 \times 0.10 + 2 \times 0.15 + 3 \times 0.60 = 2$$

Note that $min(X) \leq E[X] \leq max(X)$

Variance

Chebyshev's inequality

Example: Fair coin

- Suppose a coin is flipped and X is declared 0 or 1 corresponding to a head or a tail, respectively
- What is the expected value of X?

$$E[X] = .5 \times 0 + .5 \times 1 = .5$$

 Note, if thought about geometrically, this answer is obvious; if two equal weights are spaced at 0 and 1, the center of mass will be .5

Chebyshev's

Example: Bernoulli

- \bullet Suppose that a person is infected with the flu virus with probability θ
- 1 is "person is infected", 0 is "person is not infected"
- X takes the value 1 with probability θ and 0 with probability $1-\theta$
- What is the expected value of *X*?

$$E[X] = (1 - \theta) \times 0 + \theta \times 1 = \theta$$

• Interpretation: If one selects at random one person from a population of individuals with $100\theta\%$ infected people then the probability of this person to be infected is θ

Example: die rolls

- Suppose that a die is tossed and X is the number face up
- What is the expected value of *X*?
- X takes values in {1, 2, 3, 4, 5, 6}
- $P(X = 1) = \ldots = P(X = 6) = \frac{1}{6}$

$$E[X] = 1 \times \frac{1}{6} + 2 \times \frac{1}{6} + 3 \times \frac{1}{6} + 4 \times \frac{1}{6} + 5 \times \frac{1}{6} + 6 \times \frac{1}{6} = 3.5$$

- Again, the geometric argument makes this answer obvious without calculation
- Note that the mean **is not** the most likely value the variable takes. In this example $P\{X = E[X]\} = 0$

Varianc

Chebyshev's inequality

Using R to calculate the sample mean

Simulate the mean of n die rolls

```
mx5 <- rep (0, 1000)
mx10=mx5
mx20=mx5
mx100=mx5

for (i in 1:1000)
```

```
r ( i in 1:1000 )
{mx5[i] <- mean(sample(1:6,5,replace=T))
mx10[i] <- mean(sample(1:6,10,replace=T))
mx20[i] <- mean(sample(1:6,20,replace=T))
mx100[i] <- mean(sample(1:6,100,replace=T))}</pre>
```

Chebyshev's

Example

Values

Discrete random variables

Variables

Continuous random variables

Rules abou expected values

Variance

Chebyshev's inequality

Example: mental health

- Suppose that one observes the mental health of people in a large (n = 10,000) cohort study
- For each subject one observes one of the outcomes "healthy", "mild", "moderate", "serious"

What is the random variable and what is its mean?

Continuous random variables

Rules abou expected values

Variance

Chebyshev's inequality

Continuous random variables

• For a continuous random variable, X, with density, f(x), the expected value is defined as follows

$$E[X] = \int_{-\infty}^{\infty} x f(x) dx$$

 This definition borrows from the definition of center of mass for a continuous body

Chebyshev's inequality

Example: uniform distribution

- Consider that the random variable X has a distribution with density f(x) = 1 for $x \in [0,1]$ and 0 otherwise
- Plot f(x)
- This is called the uniform distribution and we write $X \sim U[0,1]$
- Is this a valid density?
- Suppose that X follows this density; what is its expected value?

$$E[X] = \int_0^1 x dx = \frac{x^2}{2} \Big|_0^1 = 1/2$$

- What is the pdf of the Uniform distribution on [a, b]?
- What is its mean?

Continuous random variables

expected values

Variance

Chebyshev's inequality

Example: uniform distribution

```
y1<-mean(runif(10000))
y2<-mean(runif(10000,0,10))
y3<-mean(runif(10000,-2,15))</pre>
```

- If $X \sim U(a,b)$ calculate E[X]
- If $X_1, ..., X_n$ are independent random variables with pdf f(x)

$$\overline{X}_n = \frac{1}{n}(X_1 + \ldots + X_n) \approx E[X] = \int x f(x) dx$$

• When *n* is larger the approximation is better (aka the strong law of large numbers)

Variance

Chebyshev's inequality

Distributions: the mean

- The mean is the "center of mass"; may not even be an acceptable value for experiment
- The mean is not typically the median
- For symmetric distributions (aka error distributions) the mean and the median are equal
- The mean can be heavily influenced by skewness, outliers
- Examples: medical expenditure in the US, average net worth, insurance claims
- Remember: interpretation, interpretation, interpretation

Varianc

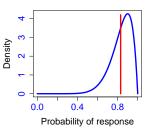

Chebyshev'

Example

Continuous random variables

Rules abou expected values

Varianc

Chebyshev's inequality

Example: Gamma distribution

 Consider that the random variable X has a distribution with density

$$f(x) = rac{1}{eta^{lpha}\Gamma(lpha)} x^{lpha-1} e^{-x/eta}, ext{ for every } x \in (0,\infty)$$

- $\Gamma(\alpha) = \int_0^\infty x^{\alpha-1} e^{-x} dx$
- Is this a valid density?
- Suppose that X follows this density; what is E[X]?
- What is $E[X^{\pi}]$?

Variance

Chebyshev's inequality

Rules about expected values

- The expected value is a linear operator
- If a and b are not random and X and Y are two random variables then
 - E[aX + b] = aE[X] + b
 - E[X + Y] = E[X] + E[Y]
 - $X \sim exp(5)$, $Y \sim U(20, 25)$. E[3X + 2Y] = ?
- In general if g is a function that is not linear,

$$E[g(X)] \neq g(E[X])$$

• For example, in general, $E[X^2] \neq E[X]^2$, $E[\log(X)] \neq \log(E[X])$

Varianc

Chebyshev's inequality

Nonlinear transformation of the mean

- We show that $E[X]^2 \le E[X^2]$ for every discrete random variable X
- This is actually true for every random variable
- We need to show $\{\sum_{x} xp(x)\}^2 \le \sum_{x} x^2p(x)$
- It is known that $(\sum_i a_i b_i)^2 \le (\sum_i a_i^2)(\sum_i b_i^2)$
- Take $a_x = x\sqrt{p(x)}$, $b_x = \sqrt{p(x)}$
- Show that $(a_1b_1 + a_2b_2)^2 \le (a_1^2 + a_2^2)(b_1^2 + b_2^2)$

In general, if $h(\cdot)$ is a convex function $h(E[X]) \leq E[h(X)]$

Varianc

Chebyshev's inequality

 You flip a coin, X and simulate a uniform random number Y, what is the expected value of their sum?

$$E[X + Y] = E[X] + E[Y] = .5 + .5 = 1$$

- Another example, you roll a die twice. What is the expected value of the average?
- Let X_1 and X_2 be the results of the two rolls

$$E[(X_1 + X_2)/2] = \frac{1}{2}(E[X_1] + E[X_2]) = \frac{1}{2}(3.5 + 3.5) = 3.5$$

length(seq(1,6,by=1/200))

Varianc

Chebyshev's inequality

Example

- 1 Let X_i for $i=1,\ldots,n$ be a collection of random variables, each from a distribution with mean μ
- 2 Calculate the expected value of the sample average of the X_i

$$E\left[\frac{1}{n}\sum_{i=1}^{n}X_{i}\right] = \frac{1}{n}E\left[\sum_{i=1}^{n}X_{i}\right]$$
$$= \frac{1}{n}\sum_{i=1}^{n}E\left[X_{i}\right]$$
$$= \frac{1}{n}\sum_{i=1}^{n}\mu = \mu.$$

Outlin

values

Discrete random variables

Continuous random variables

Rules about expected values

Variance

Chebyshev's inequality

- Therefore, the expected value of the sample mean is the population mean that it's trying to estimate
- When the expected value of an estimator is what it is trying to estimate, we say that the estimator is unbiased
- An estimator is any function of the data, U(X). A parameter is any unknown quantity in the model, θ
- U(X) is unbiased for θ if $E[U(X)] = \theta$

Outlin

values
Discrete random
variables
Continuous random
variables

Rules abou expected values

Variance

Chebyshev's inequality

• The variance of a random variable is a measure of spread

• If X is a random variable with mean μ , the variance of X is defined as

$$Var(X) = E[(X - \mu)^2]$$

the expected (squared) distance from the mean

- If X is a discrete random variable $Var[X] = \sum_{x} (x \mu)^2 p(x)$
- If X is a continuous random variable $Var[X] = \int_{-\infty}^{\infty} (x \mu)^2 f(x) dx$
- Densities with a higher variance are more spread out than densities with a lower variance

Chebyshev's inequality

The variance

Convenient computational form

$$Var(X) = E[X^2] - E[X]^2$$

- If a is constant then $Var(aX) = a^2 Var(X)$
- The square root of the variance is called the standard deviation
- $SD(X) = \sqrt{Var(X)}$
- The standard deviation has the same units as X
- If a is constant then SD(aX) = aSD(X): scale invariant
- Prove these results

 What is the sample variance from the result of a toss of a die?

- $Var(X) = E[X^2] E[X]^2$
- What are the values that X^2 can take?

Outline

Values

Discrete random variables

Continuous random variables

Rules abou expected values

Variance

Chebyshev's inequality

What is the sample variance from the result of a toss of a die?

•
$$E[X] = 3.5$$

•
$$E[X^2] = 1^2 \times \frac{1}{6} + 2^2 \times \frac{1}{6} + 3^2 \times \frac{1}{6} + 4^2 \times \frac{1}{6} + 5^2 \times \frac{1}{6} + 6^2 \times \frac{1}{6} = 15.17$$

• $Var(X) = E[X^2] - E[X]^2 \approx 2.92$

```
x=1:6
ex2=sum(x^2*rep(1/6,6))
ex=sum(x*rep(1/6,6))
varx=ex2-ex^2
```

Variance

Chebyshev's inequality • What's the sample variance from the result of the toss of a coin with probability of heads (1) of p?

•
$$E[X] = 0 \times (1 - p) + 1 \times p = p$$

•
$$E[X^2] = E[X] = p$$

•
$$Var(X) = E[X^2] - E[X]^2 = p - p^2 = p(1-p)$$

Table of contents

Outlin

Expected
values

Discrete random
variables

Continuous random
variables

Rules abou expected values

Variance

Chebyshev's inequality • Suppose that a random variable is such that $0 \le X \le 1$ and E[X] = p

- Note that $X^2 \le X$ so that $E[X^2] \le E[X] = p$
- $Var(X) = E[X^2] E[X]^2 \le E[X] E[X]^2 = p(1-p)$
- Therefore the Bernoulli variance is the largest possible for random variables bounded between 0 and 1
- Largest variance is attained at p = 0.5
- For every Beta distribution there exists a Bernoulli distribution with the same mean and larger variance

Continuous rando variables

Rules about

values

Variance

Chebyshev's inequality

Interpreting variances

- Chebyshev's inequality is useful for interpreting variances
- This inequality states that

$$P(|X - \mu| \ge k\sigma) \le \frac{1}{k^2}$$

• For example, the probability that a random variable lies beyond k standard deviations from its mean is less than $1/k^2$

$$2\sigma \rightarrow 25\%$$
 $3\sigma \rightarrow 11\%$
 $4\sigma \rightarrow 6\%$

 Note that this is only an upper bound; the actual probability might be quite a bit smaller Discrete random variables

Continuous random

Rules about expected values

Variance

Chebyshev's inequality

Proof of Chebyshev's inequality

$$P(|X - \mu| > k\sigma) = \int_{\{x:|x - \mu| > k\sigma\}} f(x)dx$$

$$\leq \int_{\{x:|x - \mu| > k\sigma\}} \frac{(x - \mu)^2}{k^2\sigma^2} f(x)dx$$

$$\leq \int_{-\infty}^{\infty} \frac{(x - \mu)^2}{k^2\sigma^2} f(x)dx$$

$$= \frac{1}{L^2}$$

Rules abou expected values

Variance

Chebyshev's inequality

- IQs are often said to be distributed with a mean of 100 and a sd of 15
- What is the probability of a randomly drawn person having an IQ higher than 160 or below 40?
- Thus we want to know the probability of a person being more than 4 standard deviations from the mean
- Thus Chebyshev's inequality suggests that this will be no larger than 6%
- IQs distributions are often cited as being bell shaped, in which case this bound is very conservative
- The probability of a random draw from a bell curve being 4 standard deviations from the mean is on the order of 10^{-5} (one thousandth of one percent)

Rules abou expected values

Variance

Chebyshev's inequality

- A popular buzz phrase in industrial quality control is Motorola's "Six Sigma" whereby businesses are suggested to control extreme events or rare defective parts
- Chebyshev's inequality states that the probability of a "Six Sigma" event is less than $1/6^2\approx 3\%$
- If a bell curve is assumed, the probability of a "six sigma" event is on the oder of 10^{-9} (one ten millionth of a percent)

variables Continuous randor variables

expected values

Varianc

Chebyshev's inequality

Coefficient of variation

• For a variable X > 0

$$C_{\nu}(X) = \frac{\mathrm{SD}(X)}{E[X]}$$

- Measures the amount of variability (as described by the standard deviation) relative to the mean
- C_v is the inverse of the signal-to-noise ratio
- It does not have units (mean and standard deviation are on the same scale)
- Strong link to Cohen's d used in sample size calculations

$$C_d = \frac{E[X_1] - E[X_2]}{SD}$$

Variance
